

Competition and coexistence

Annie Schiffer

2026-07-22

Learning objectives

1. Know the processes that lead to species coexistence
2. Add a competitor to the Beverton-Holt model
3. Perform an invasion analysis

Competition and coexistence

Interspecific competition and its outcomes

- interspecific competition: one species has reduced growth rate in presence of another species
- outcomes:
 - competitive exclusion - one species outcompetes other species
 - coexistence - stabilize and both persist in long term *may have lower population growth or sizes compared to those without competitor, but if they persist, it's coexistence*
 - priority effects - depends on species arrival *whichever arrives in the community first*

given that species compete with each other, how do you get diverse communities where many species coexist?

Processes leading to stable coexistence

- spatial heterogeneity - good and bad patches

(a)

- temporal heterogeneity - good years and bad years

- resource partitioning - limited by different resources

- natural enemies - host-specific *talk about this in week 8*

species is limiting itself more than others- this makes sense because if multiple species are going to coexist, we can't have a species that has unrestricted growth, it'll just use up all the resources

- intraspecific competition > interspecific competition

Modeling interspecific competition

add to beverton-holt, previously:

$$N_{i,t+1} = \frac{\lambda N_{i,t}}{1 + \alpha_{ii} N_{i,t}}$$

add a second species to restrict population growth

- species i and j
- α_{ij} = effect of j on i

$$N_{i,t+1} = \frac{\lambda N_{i,t}}{1 + \alpha_{ii} N_{i,t} + \alpha_{ij} N_{j,t}}$$

we just added another term in the denominator, added subscripts to clarify which population we're modeling

Invasion analyses

I said you have coexistence when both persist in long term

but a time series of populations alone can't tell you if there's coexistence

plot example with 2 populations fluctuating over time

this looks like coexistence, but what if transient dynamics, decline in future?

- both species increase from low density
- long-term average population growth rate
- $\log \frac{N_{t+1}}{N_t} > 0$ for each species - coexistence, < 0 competitive exclusion
